EM Basic - Non-Pregnant Vaginal Bleeding

(Typically these questions; also sets the stage for your pelvic exam.

**PEARL:** Consider keeping quasi-stable patient in monitored room (vs. gyn ro and use a flipped over bedpan to elevate buttocks for makeshift gyn bed

Press large swab sticks, extra gauze

Gentle insertion of lubricated, approp. sized speculum

Don’t forget to explain every move you make

Chaperones for all patients, always, without exception

Order: Inspect visually, use swab stick, then do bimanual

**PEARL:** If a pregnant patient is unstable or has a concerning abdominal exam they need an immediate OB/GYN consultation and the OR.

**Differential Diagnosis**

Break down by Extra GU vs. not, then sort by menstrual status

**Extra-GU Causes**

- Labial/skin tear
- Hemorrhoids
- Vulvar lesions
- Rectovaginal fistula
- Cystitis/UTI

**Pre-pubertal**

- Neonate: Estrogen withdrawal bleed, 3d-3wk; reassure/educate
- Most common: Vulvovaginitis (Streptococcal, environmental, non-specific)
- Rule out: Trauma, foreign body, abuse
- FB: Ask about bad smell, time course

**Pre-menopausal** - arrange by painful/non-painful

- Painful: Ruptured ovarian cyst, PID, ovarian torsion, ruptured endometrioma, trauma, abuse

**PEARL:** torsion RARELY presents with bleeding

- Painless: Cancer, coagulation disorder (esp. in 10s-30s age), non-malignant structural causes (leiomyoma, polyps, etc.), AUB, ovulato

**UB**

**PEARL:** Anovulatory uterine bleeding is 90% of painless VB, but is or diagnosed when you are confident it is not malignant/structural anc not from elsewhere in GU tract

- Ovulatory uterine bleeding: “Really horrible period”

**Post-menopausal**

- Cancer- both Gyn and don’t forget hematologic (leukemias)
  - Again think anatomically- ovaries/tubes/uterus/vagina

- Medication (supratherpeutic INR, novel anticoagulants, HRT)

- Non-malignant structural causes

- Atrophic vaginitis

**STABLE PATIENT (vast majority of ED vaginal bleeding)**

**History**

- Amt of blood/clots: Get objective information (pads/hr, dimensions of clots vs. mild spotting)
- Weakness, lightheaded, SOB, chest pain? – helps with determining plan
- Liver, renal, CV, heme disease? – Consider coagulopathy, hx of CAD/MI that could be affected by anemia, hx of VTE could affect treatment, etc.
- Pain
- Meds

**PEARL:** Ask specifically about IUD/Nexplanon, anticoagulating meds, chronic hormonal exposure

**Focused Gyn Hx (5 simple questions):**

1.) G’s and P’s: Ever pregnant, what were outcomes?
2.) Are you menstruating, when was LMP?
3.) Any abnormal Pap, gyn surgeries, or procedures done?
4.) Sexually active, any hx of STI?
5.) Anything else in personal/family gyn history? Allow 5-10 seconds to get a really good answer—pt needs time to think here

**PEARL:** 99% of the time it is best to get other people out of room when asking these questions; also sets the stage for your pelvic exam.

**Associated signs and symptoms**

- Abdominal pain, nausea/vomiting, discharge
- Chest pain, SOB, dizziness, near syncope/syncope

**Exam**

- Eyeball: is pt diaphoretic, pale, exsanguinating, altered ment. status?
  - move to resuscitate
- General exam: Heart, lungs, sit/stand/walk patient as needed
- Abdominal: distention, dusky, color changes/bruising, peritoneal signs
- Gyn

**Episode written by Dr. Adaira Landry (EM senior resident, Bellevue) and Joseph Kennedy (MS-4, Mayo Clinic)**

**Immediately**

- Assess stability; move to resuscitate if indicated

Workup

Most patients only need...

UA (check for UTI, b-HCG for pregnancy status)

CBC (consider repeat at 3-4 hrs if you are observing)
  + differential if any concern for malignancy (leukemia)

Looking potentially sick?

Type and screen; move to cross-match if symptomatic + anemic

On warfarin, hx of liver disease?

PT and INR

Abnormal finding on gyn exam?

GC/Chlamydia

Symptomatic anemia + chest pain?

ECG, consider ACS and appropriate r/o MI work-up

Imaging?

Transabdominal + transvaginal pelvic US is good first line, though not-needed in most patients in the ED (get as outpatient)

Rx for Outpatient Management

Estrogen/Progestrone based therapy:

ACOG recs: Medroxyprogesterone acetate, 20 mg TID for 7 days

Or try: OCP taper: find an OCP with 35 mcg ethinyl estradiol

</table>

Give anti-emetic (e.g. promethazine, 12.5-25 mg PO or PR, PRN)

PEARL- NO hormonal therapy in ED if hx of VTE or VTE risk factors, early post-partum, age >35 and smoker, multiple CV risk factors, active cancer, drug interactions (rifampin, anticonvulsants, antiretroviral), etc.

Great reference: List of Everything that Complicates OCPs

Adjunct

NSAIDS: ↑ prostaglandins facilitate uterine vasoconstriction

Iron: Cheap/easy is ferrous sulfate, 325 mg TID between meals; warn of black stools and potential for GI upset

Disposition

If sending home, give strict return precautions (return if <1 pad/hr, large clots, headaches, dizzy, etc.)

Always refer to gyn for postmenopausal bleeding to work-up for malignancy

Special Circumstances

1.) Continuously symptomatic/mod bleed/mod vitals: repeat labs in 4 hours or sooner if they decompensate

2.) Pregnant: If you somehow find +b-Hcg, do a workup to document intrauterine pregnancy

3.) Sexual abuse: Get social work, protective svc. on board early

4.) Foreign objects: Remove prior to discharge, get gyn if needed

5.) Admit if continuously symptomatic, transfusions required, serial H&H required, or definitive surgical care is indicated

UNSTABLE PATIENT

Assemble a team early, notify someone that blood MIGHT be needed,

Get access and draw labs:

  - CBC with diff
  - HCG
  - Type and screen
  - Basic metabolic panel
  - Coagulation panel
  - Venous lactate

Place 2x IV, preferably 16 gauge or better

Do not hesitate to move to IO catheter placement if needed

Protect yourself: Gloves/face shield/gown

Grab supplies to tamponade bleeding:

  - Sterile gloves
  - Kerlix gauze and 4x4s
  - Bottle of betadine
  - Abdominal pads
  - Diapers
  - Foley catheter (24 French, and also get a large syringe and 60-120cc more of saline to fill the bulb of the Foley)
  - Sengstaken-Blakemore tube or Bakri catheter + ring forceps

Pack uterus with betadine-soaked gauze, give plenty of fast-acting analgesia (i.e. fentanyl) while instrumenting the vagina and uterus
Take a look with tranabdominal US and consider FAST exam
   Nice guide to FAST: Click here
   If free fluid + unstable + vaginal bleed -> PT GOES TO OR

Now, take very focused hx
   Hx of cancer or other bleeding problems?
   Any anticoagulating medication?
   Ever bled like this previously?
   Pregnant?
   At risk for abuse?

BIG POINTS
1.) If stable, get hx of anticoagulating/hormonal meds, liver/renal/CV disease, quantified amount of bleeding, 5 key gyn questions.
2.) Always probe for trauma/abuse, easier to do when you are about to do the gyn exam and everyone is out of the room.
3.) Infant/child: rule out foreign body, trauma, abuse. Older: rule out trauma, then think painful vs. painless causes. Post-menopausal: think cancers
4.) Dispo: consider how symptomatic, and observe if she’s on the threshold. If going home, don’t forget to check contraindications to OCPs!
5.) To resuscitate VB: early IV access, load the boat, and consider using a big Foley, Bakri catheter, gauze/betadine to tamponade.
